## Field data:

Armin Wisthaler (P3-B  $\text{NH}_3$ , Innsbruck)

John Nowak (C-130  $\text{NH}_3$ , Aerodyne)

Da Pan, Kang Sun, Lei Tao, Levi Golston, Lars Wendt (mobile  $\text{NH}_3$ , Princeton)

Cody Fleishcer (mobile  $\text{NH}_3$ , Aerodyne)

Rainer Volkamer (mobile FTIR  $\text{NH}_3$ , Univ. Colorado)

Anne Thompson, Bill Brune (sondes, Penn State)

Steve Brown (BAO tall tower, NOAA CSD)

Jennifer Murphy ( $\text{NH}_3$  BAO tower, Univ. Toronto)

Erik Olson (sondes, Univ. Wisc.)

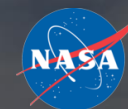

NASA DISCOVER-AQ, NSF FRAPPE science teams

## Funding

NASA NNX-NNX14AT36G

Network of  
Satellite Application  
Facilities

**O3M SAF**  
Ozone and Atmospheric  
Chemistry Monitoring

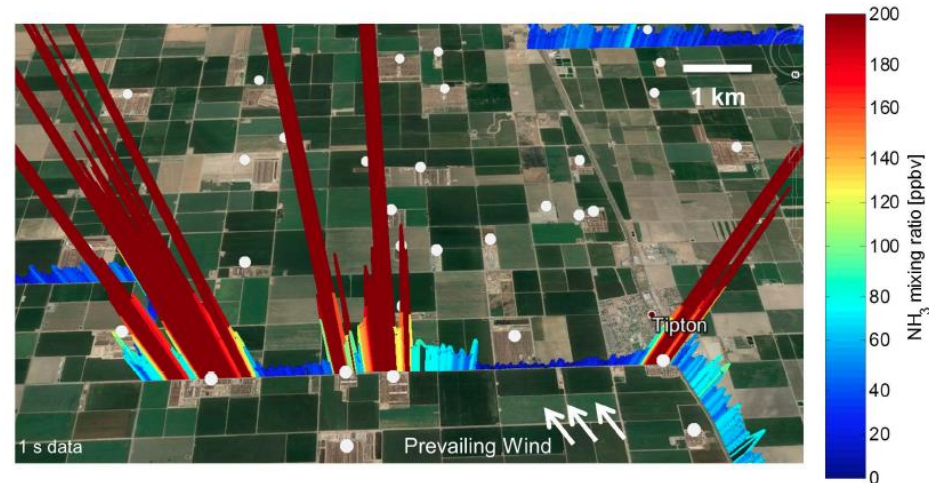

# Why $\text{NH}_3$ ?

- human health: key precursor for  $\text{PM}_{2.5}$
- ecological: nitrogen deposition, eutrophication
- chemistry: aerosol nucleation, growth, composition
- climate: ammoniated aerosols cool locally

## Challenges

- $\text{NH}_3$  incredibly difficult to measure
  - low mole fractions ( $\sim$  pptv-ppbv)
  - large dynamic range
  - adsorption to inlets/instruments
  - gas/aerosol phase partitioning

Limited datasets in which to validate recent advances in satellite  $\text{NH}_3$

# satellite $\text{NH}_3$ validation advances

## IASI:

in-situ:  $m=0.18$ ,  $r=0.82$ ,  $\pm 1$  hour in  $[\text{NH}_3]$  (Van Damme et al., AMT, 2015)

FTIR NDAAC:  $m=0.74$ ,  $r=0.7$  at 90 min., 25 km (Dammers et al., ACPD, 2016)

## NASA TES:

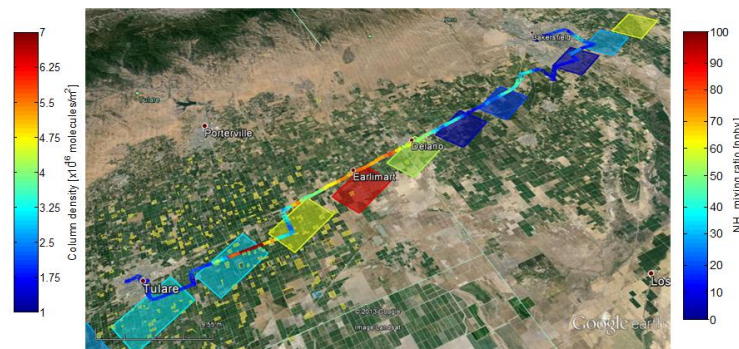

15% with in-situ @ select pixels but at high  $\text{NH}_3$  (mid  $10^{16}$  molec  $\text{NH}_3 \text{ cm}^{-2}$ )  
(Sun et al., JGR-A, 2015)

## NOAA CrIS:

simulated profiles, qualitative agreement  
at pixel (Shephard & Cady-Pereira, AMT, 2015)

## NASA AIRS:

qualitative comparisons with aircraft (Warner, ACPD, 2015)

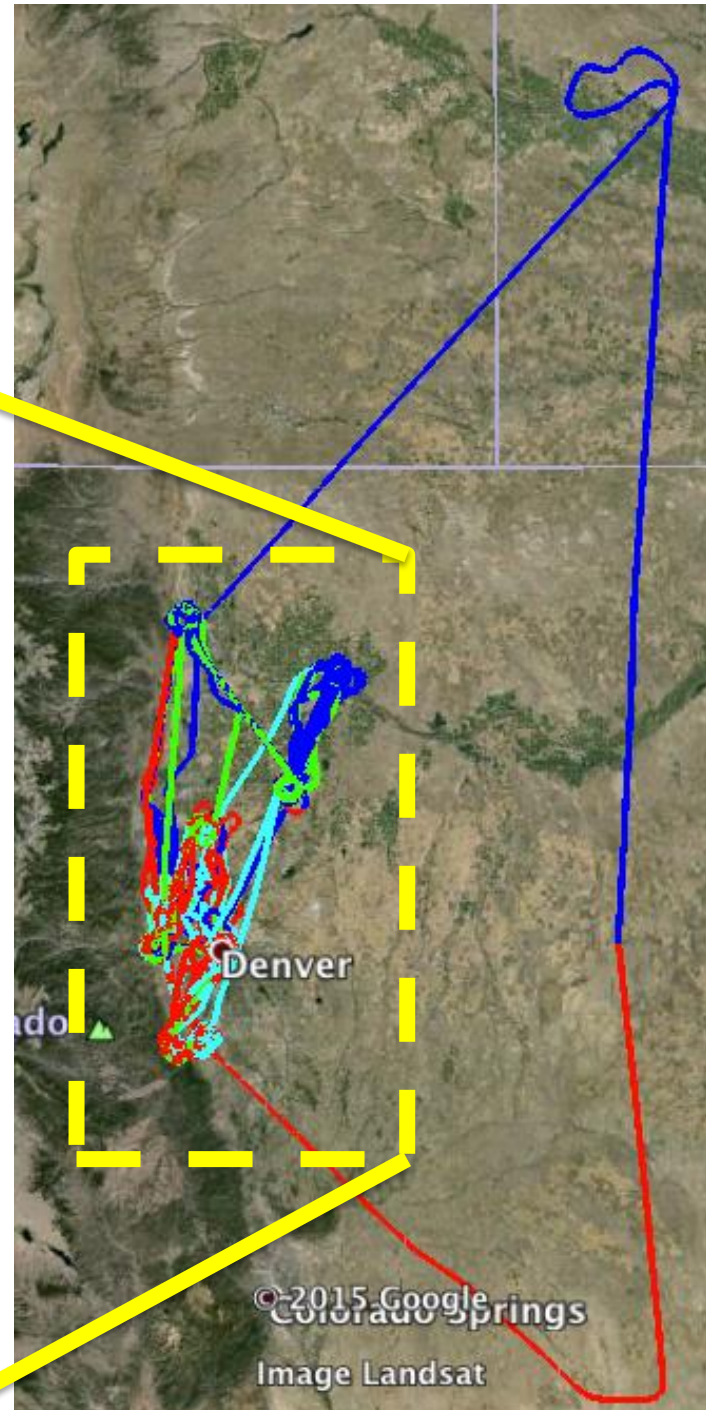

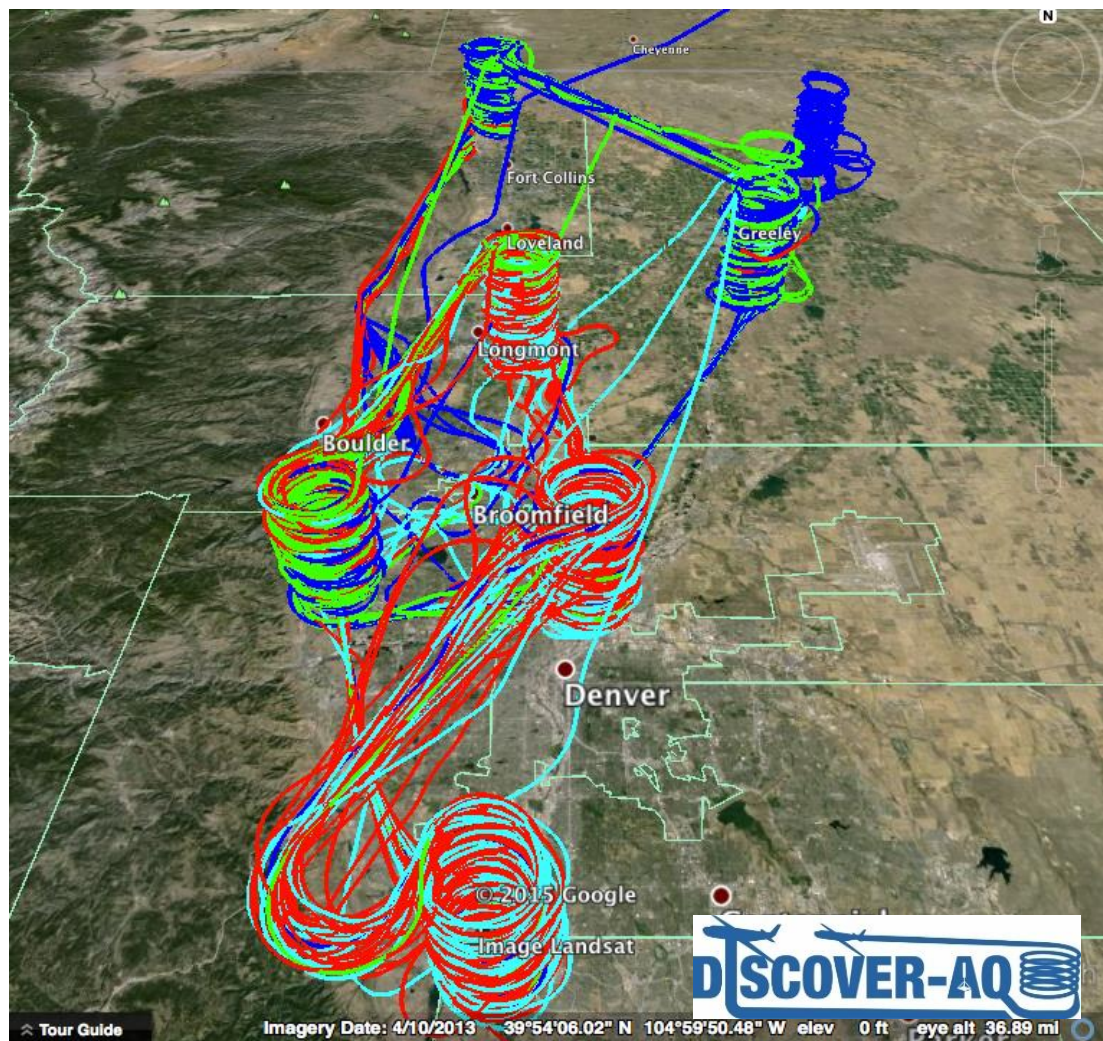

**Validation limited to spatial/monthly averaging, chemical transport model simulations, or in regions of very high-concentrations**

**To what extent do  $\text{NH}_3$  columns intercompare with in-situ at pixel scales?  
... at moderate mole fractions?**

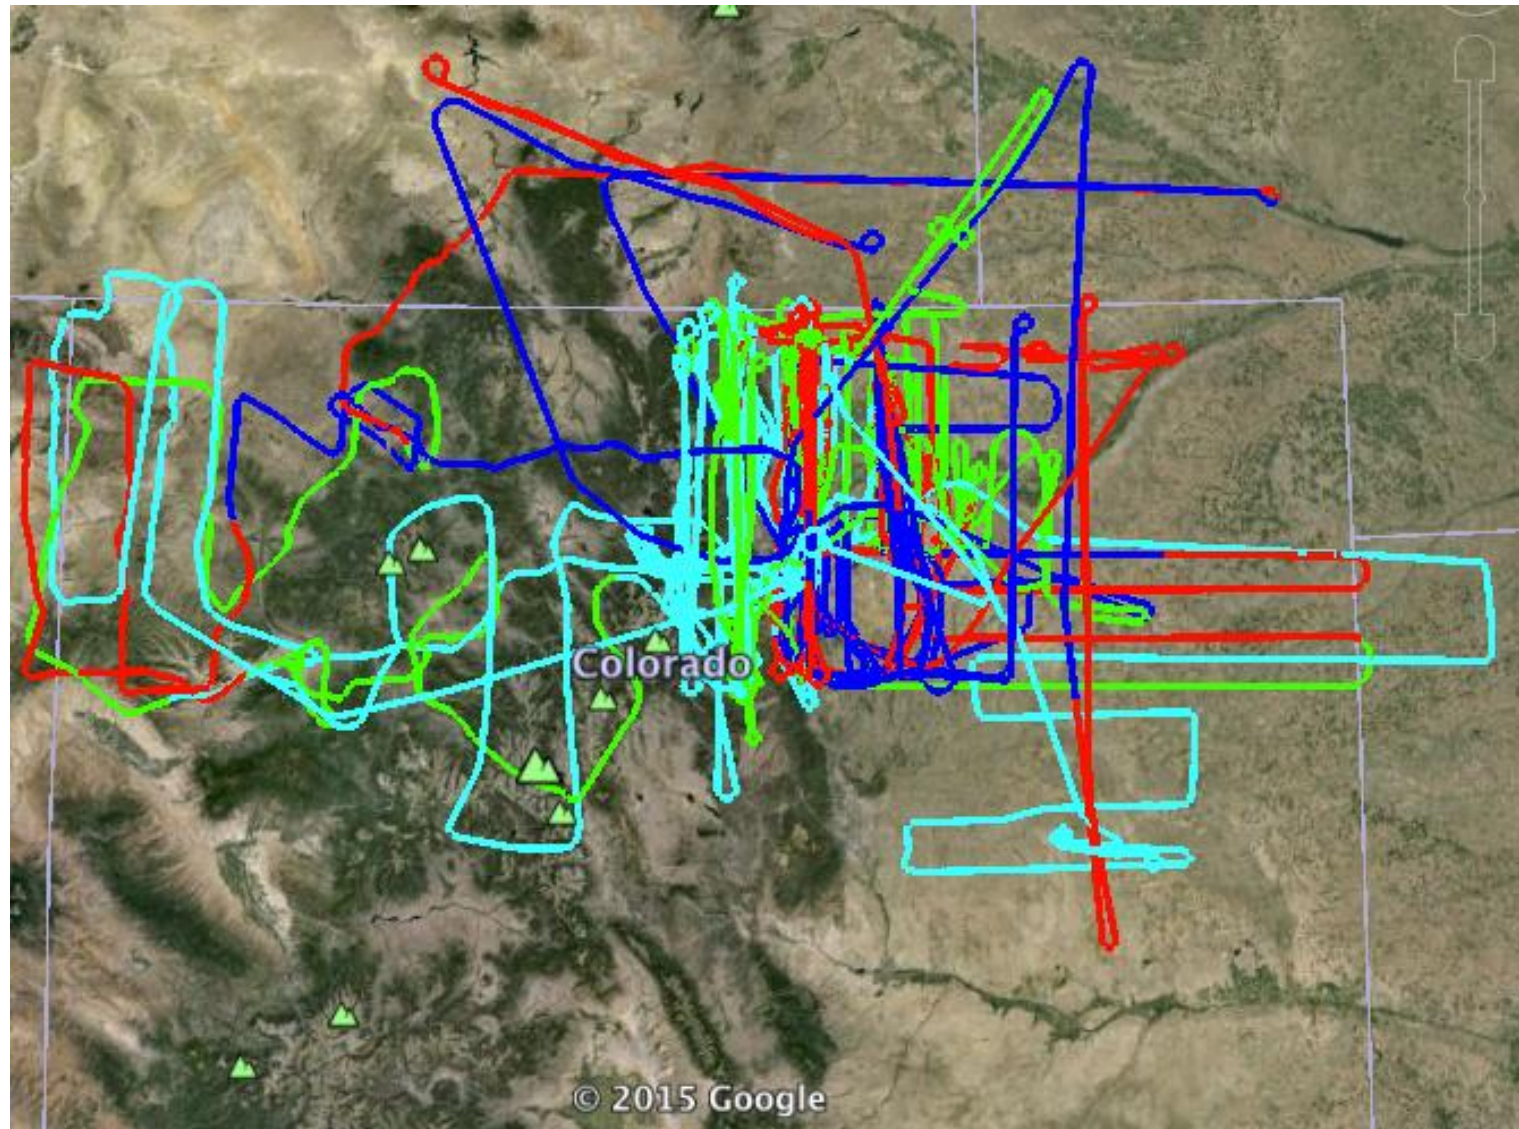

# NASA DISCOVER-AQ (DAQ)

- repeated spiral profiles along same circuit
- take off at ~ 0830 local (July-Aug 2014)
- 2-3 circuits per day
- excellent flight pattern for IASI validation

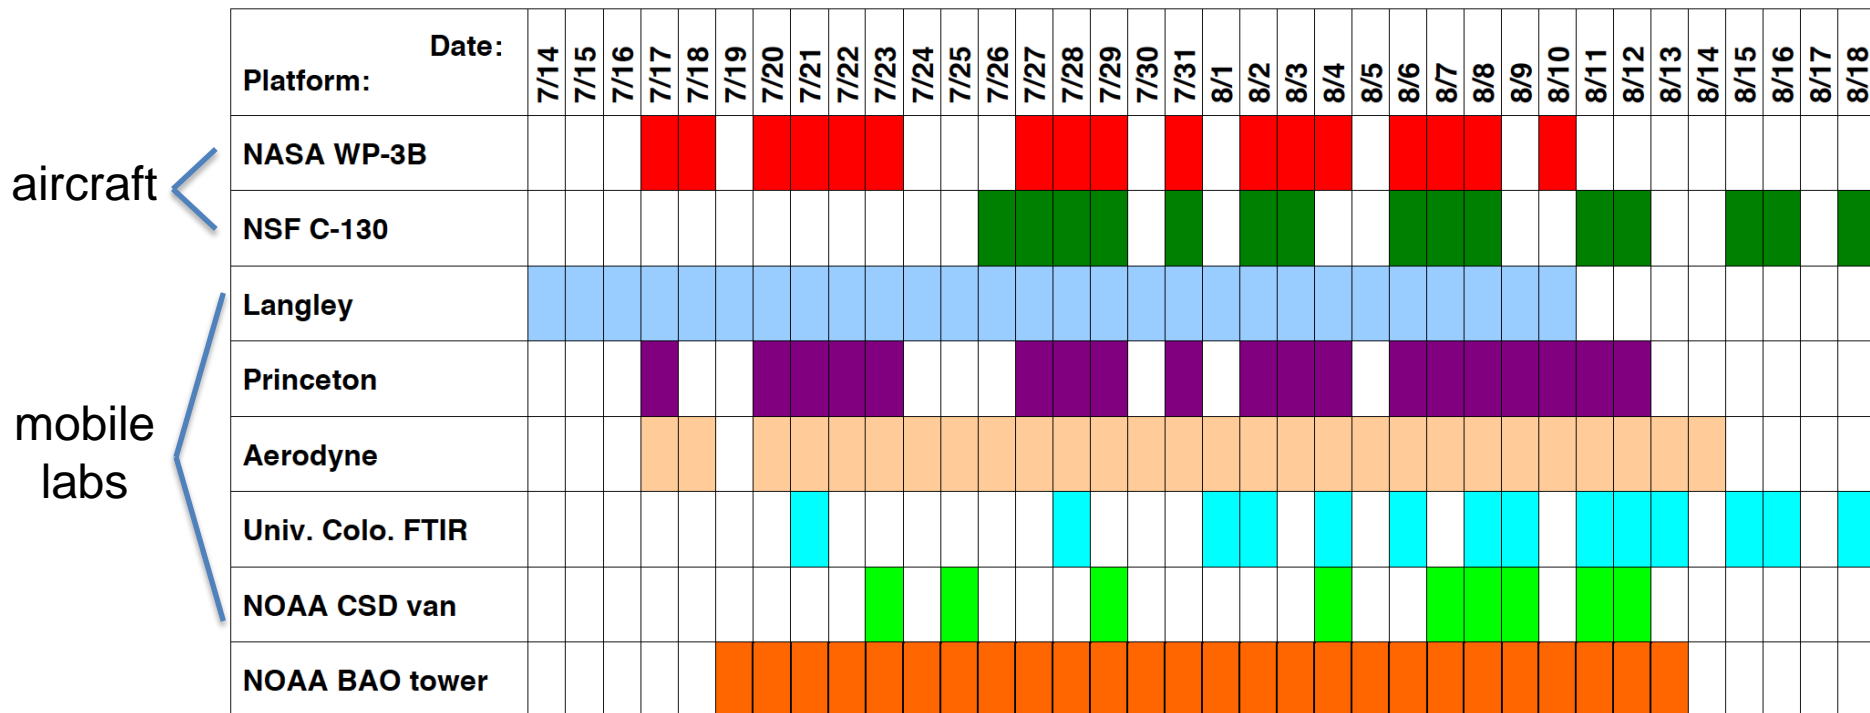

# NSF FRAPPE

- focus on (largely) horizontal gradients and temporal evolution of the gradients
- takeoff ~ 0900 local
- constant altitude legs (some vertical profiles)

# Additional in-situ NH<sub>3</sub> measurements

## NH<sub>3</sub> measurements during DISCOVER-AQ/FRAPPE in Colorado:

<u>platform</u>	<u>avg. uncertainty</u>	<u>method</u>	<u>PI</u>
P3-B	30%	PTRMS	A. Wisthaler (Innsbruck)
C-130	34% + 0.39 ppbv	TDL	J. Nowak (Aerodyne)
Aerodyne mob.	34% + 0.39 ppbv	TDL	C. Floerchinger (Aerodyne)
Princeton mob.	20% + 0.4 ppbv	Open-path	M. Zondlo (Princeton)
CU column	10%	FTIR	R. Volkamer (CU)
NOAA/CSD	20% + 0.3 ppbv	Picarro	A. Neuman (NOAA CSD)
NOAA/BAO	20% + 0.3 ppbv	Picarro	J. Murphy (Univ. Toronto) / S. Brown (NOAA CSD)

# IASI MetOp/A $\text{NH}_3$ during DAQ/FRAPPE

Time: 7/14/14-8/18/14

Spatial: 38-42°N to 101-109.5°W

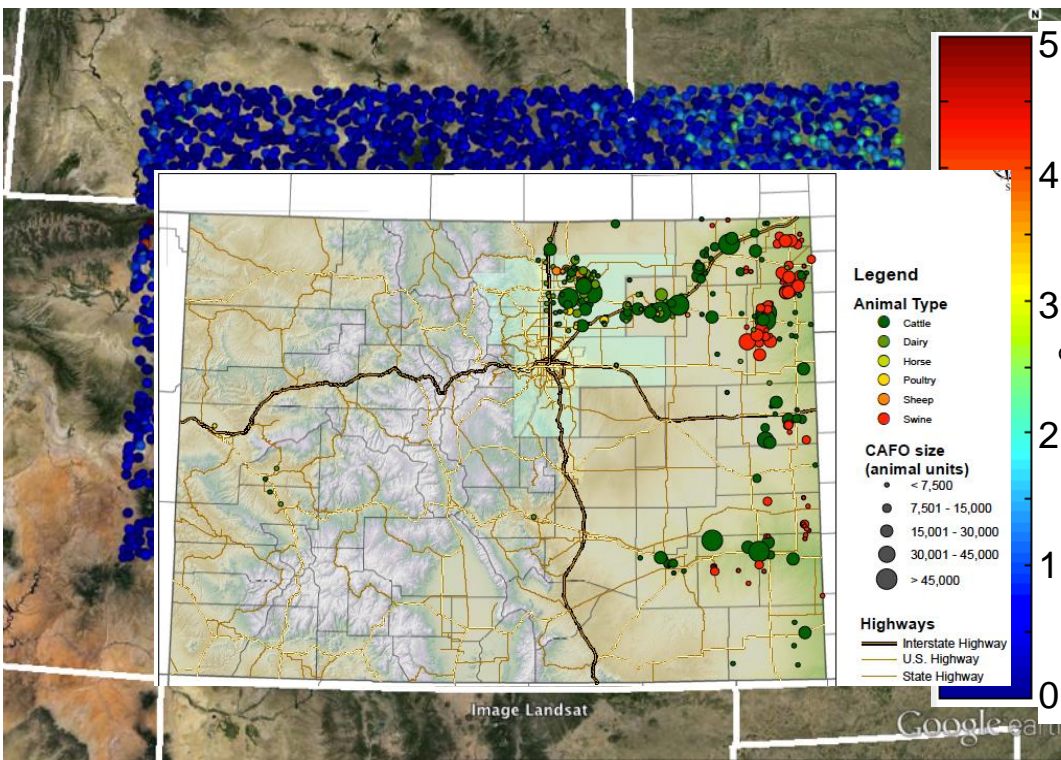

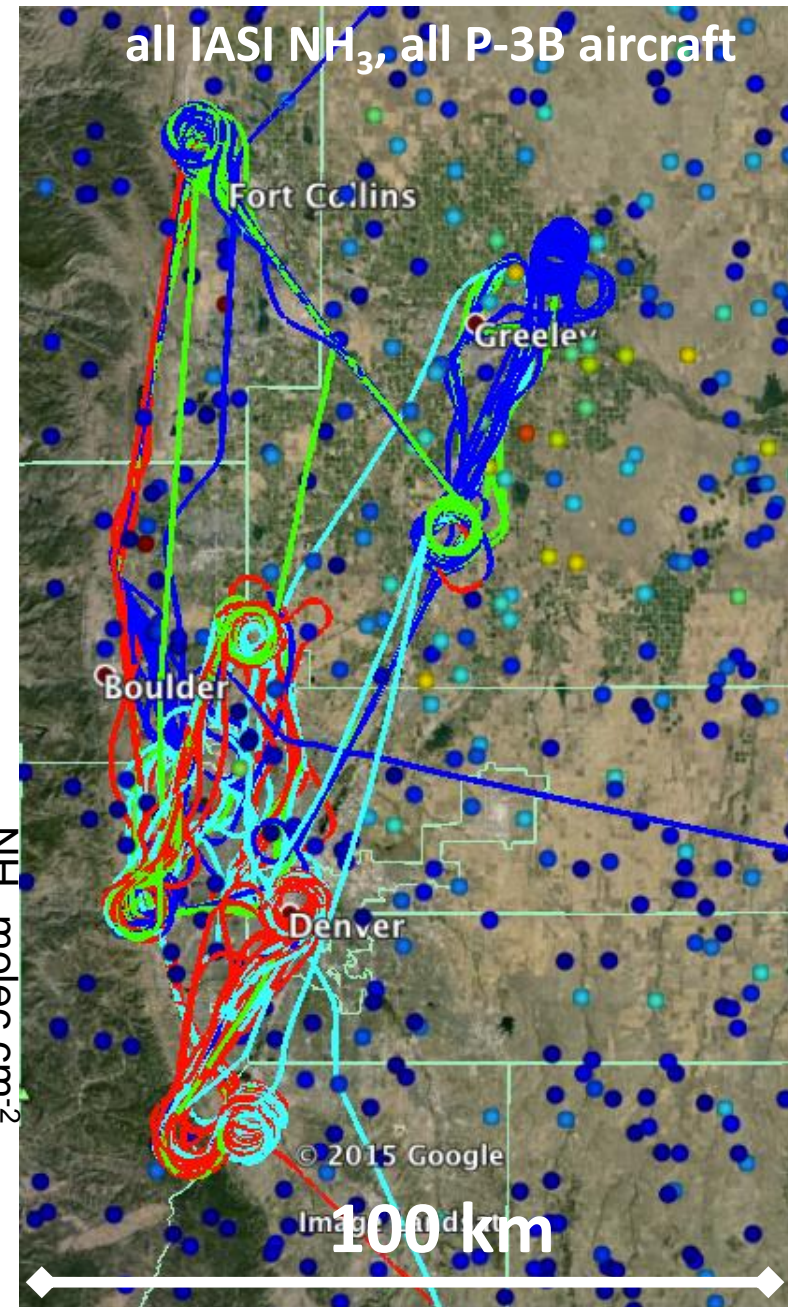

IASI Neural Network (*Whitburn et al., JGR-A, 2016*)

N=11,760 IASI  $\text{NH}_3$  measurements (AM only)

N=6,371 filtered IASI  $\text{NH}_3$

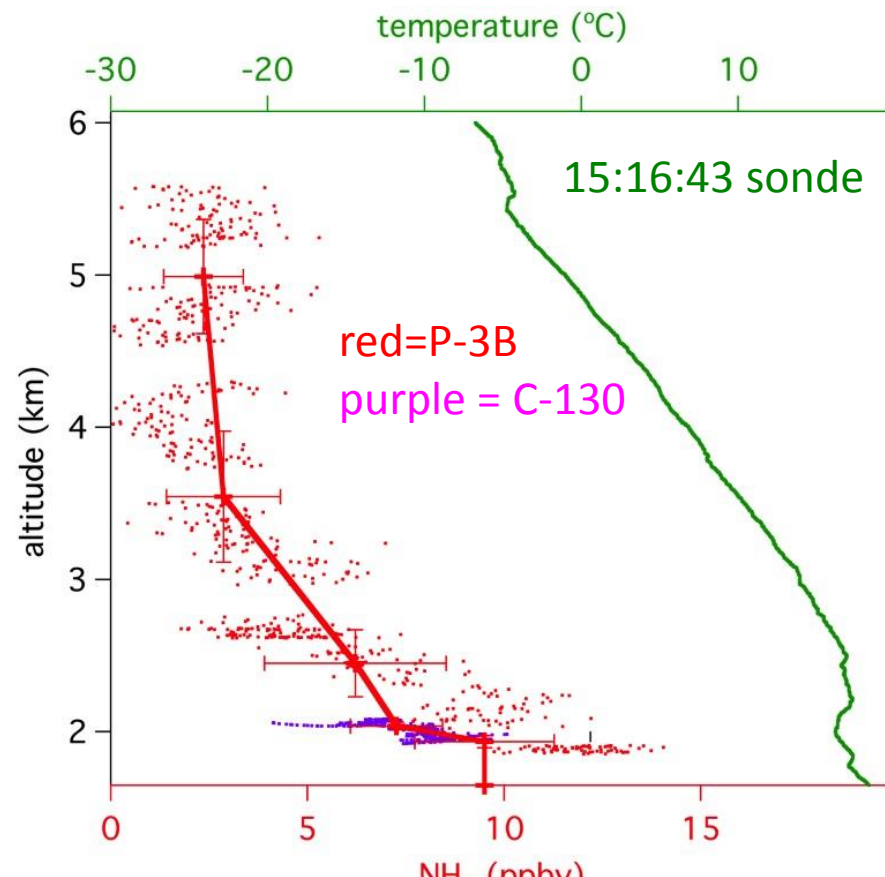

(cloud < 25%, sand < 50%,  $T_{\text{skin}} > 265.15 \text{ K}$ ; error < 200%)

N=64 ( $\pm 60 \text{ min}$ ,  $\pm 15 \text{ km}$  with in-situ profiles)

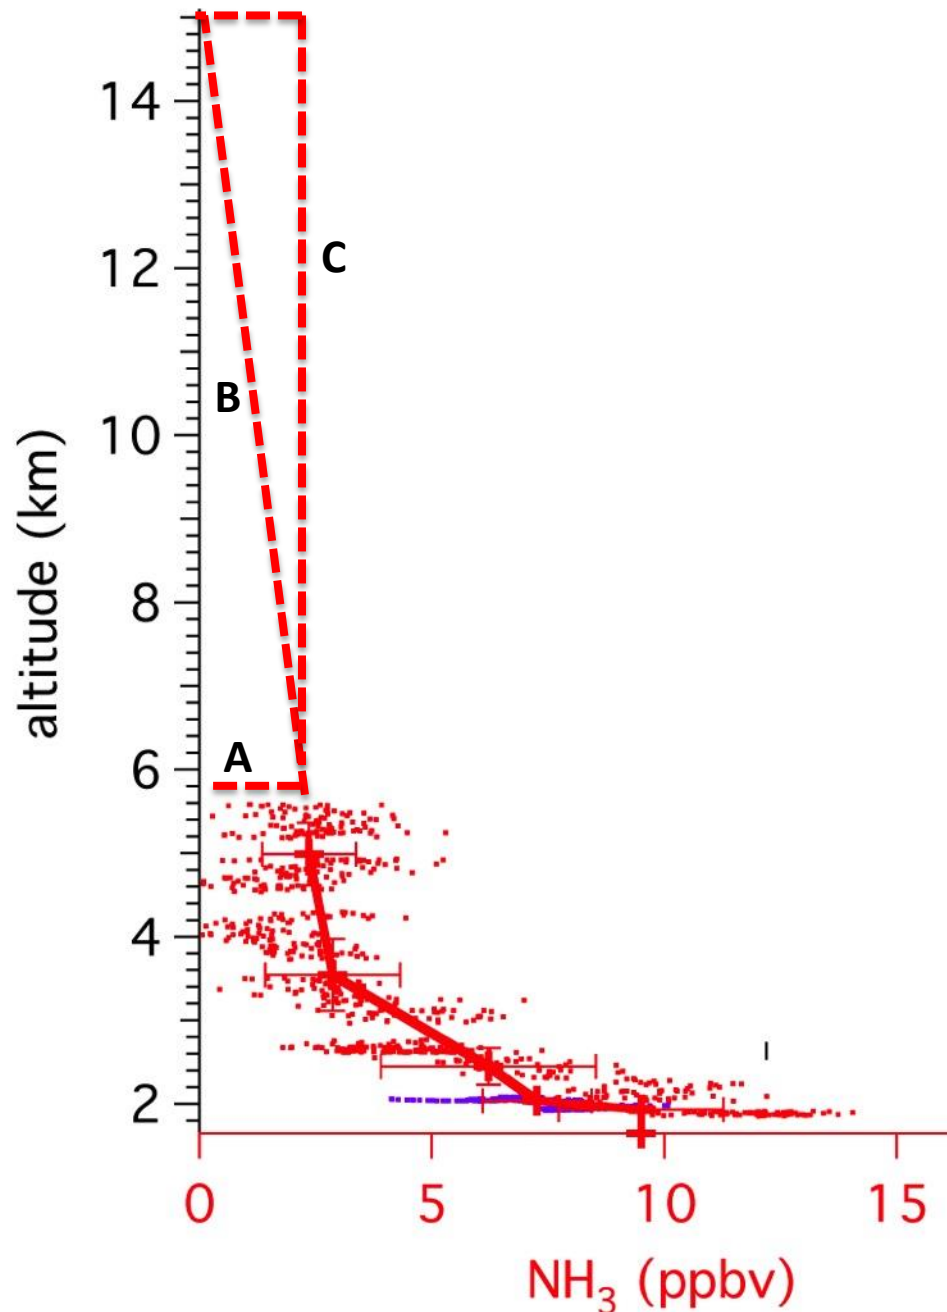

# in-situ-derived column comparison method

- identify all in-situ data within space / time window of  $\pm 15$  km, 60 min.  
(consistent with  $4 \text{ m s}^{-1}$  mean wind speed in boundary layer)
- data binned within  $\pm 100$  m of ground and at 500 m bins above
- $\text{NH}_3$  molecular density derived from nearly sonde
- trapezoidal integration of column
- “profile”: in-situ data  $< 500$  m of ground and at least  $> 1.5$  km altitude
- profile uncertainties derived from in-situ measurement uncertainties

# Aircraft-derived column uncertainties

Assumptions:

- 1) no  $\text{NH}_3$  at  $z > 15$  km  
(i.e. in stratosphere)
- 2) extrapolate lowest  $\text{NH}_3$  bins to ground
- 3) no  $\text{NH}_3$  spatiotemporal gradients in window
- 4) mid/upper troposphere for  $\text{NH}_3(z)$  for  $z > 5$  km:

Case A:

No  $\text{NH}_3$  above highest plane altitude  
Total column =  $2.6 \times 10^{16}$  molec  $\text{cm}^{-2}$

Case B:

Linear  $\text{NH}_3$  decrease to tropopause  
Total column =  $3.7 \times 10^{16}$  molec  $\text{cm}^{-2}$

Case C:

Constant  $\text{NH}_3$  from 5 km to tropopause  
Total column =  $5.5 \times 10^{16}$  molec  $\text{cm}^{-2}$

IASI column =  $1.2 \times 10^{16} \pm 26\%$

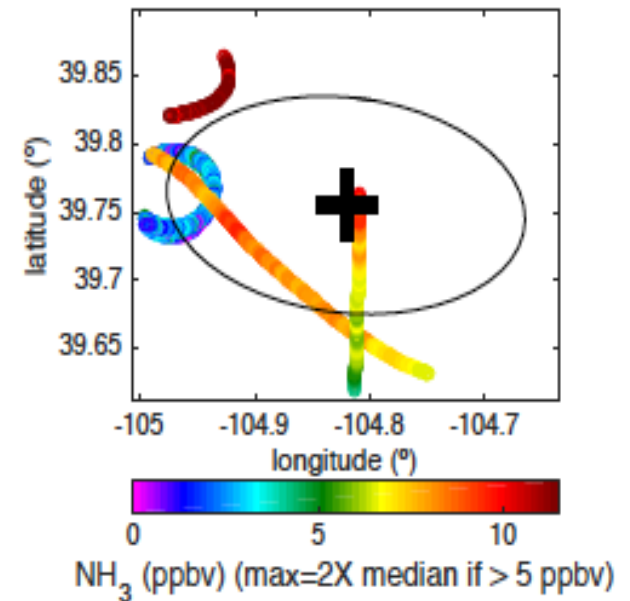

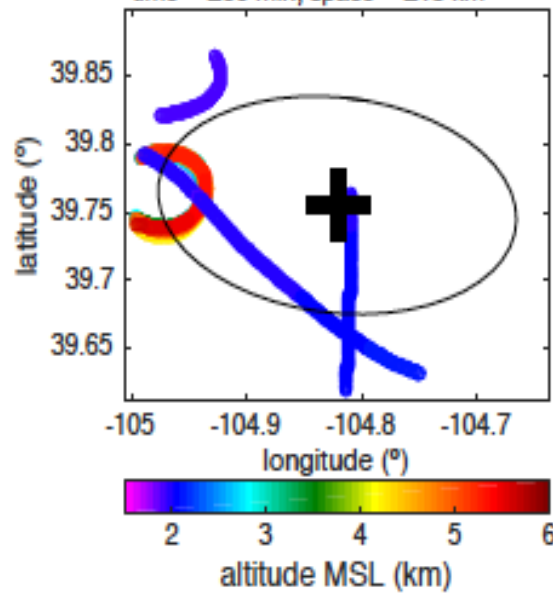

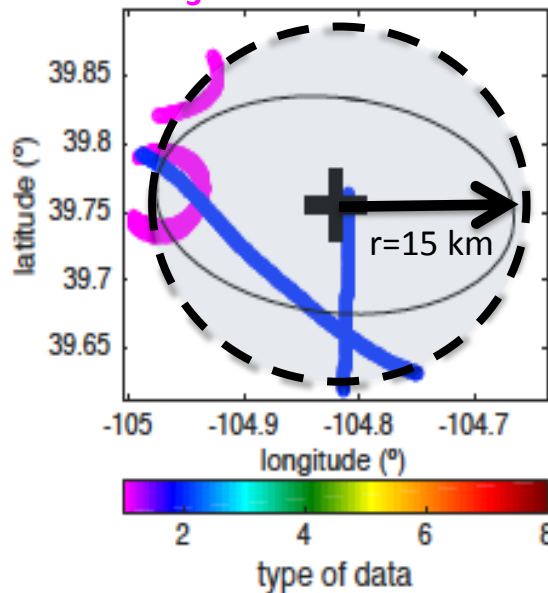

# Moderate column case study

C-130 NH<sub>3</sub>

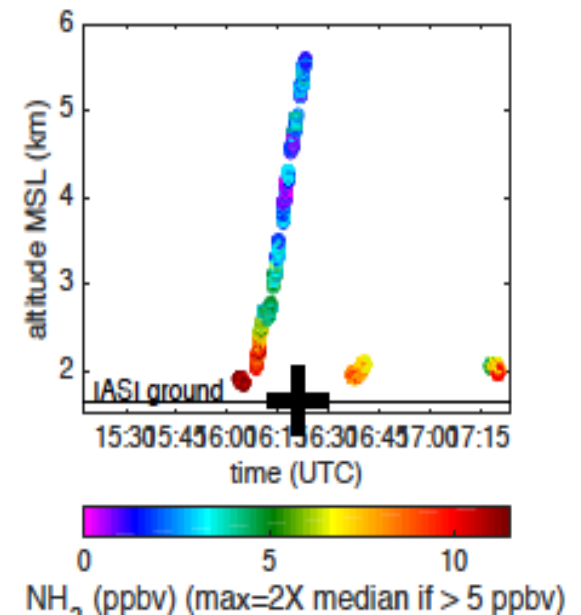

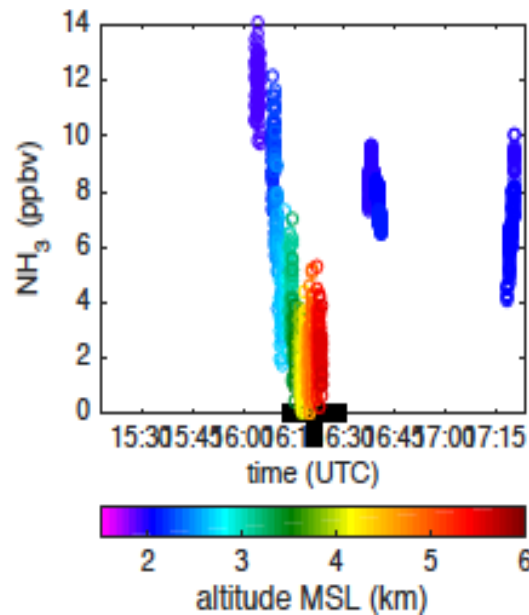

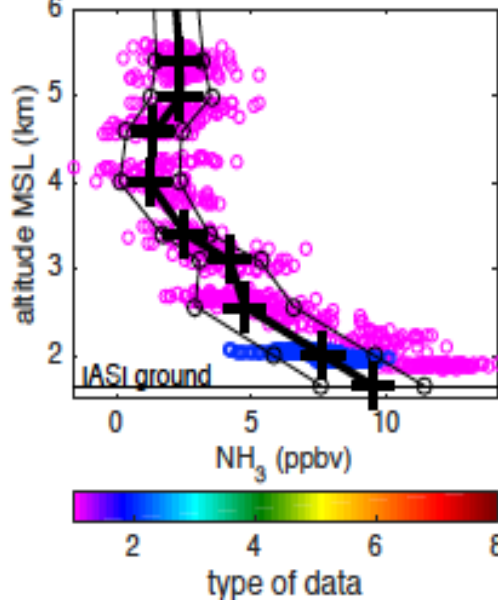

P-3B NH<sub>3</sub>

NH<sub>3</sub> col:  $1.17 \times 10^{16} \text{ molec cm}^{-2} \pm 25.6\%$   $i=213$   $\text{fov}=110^\circ$

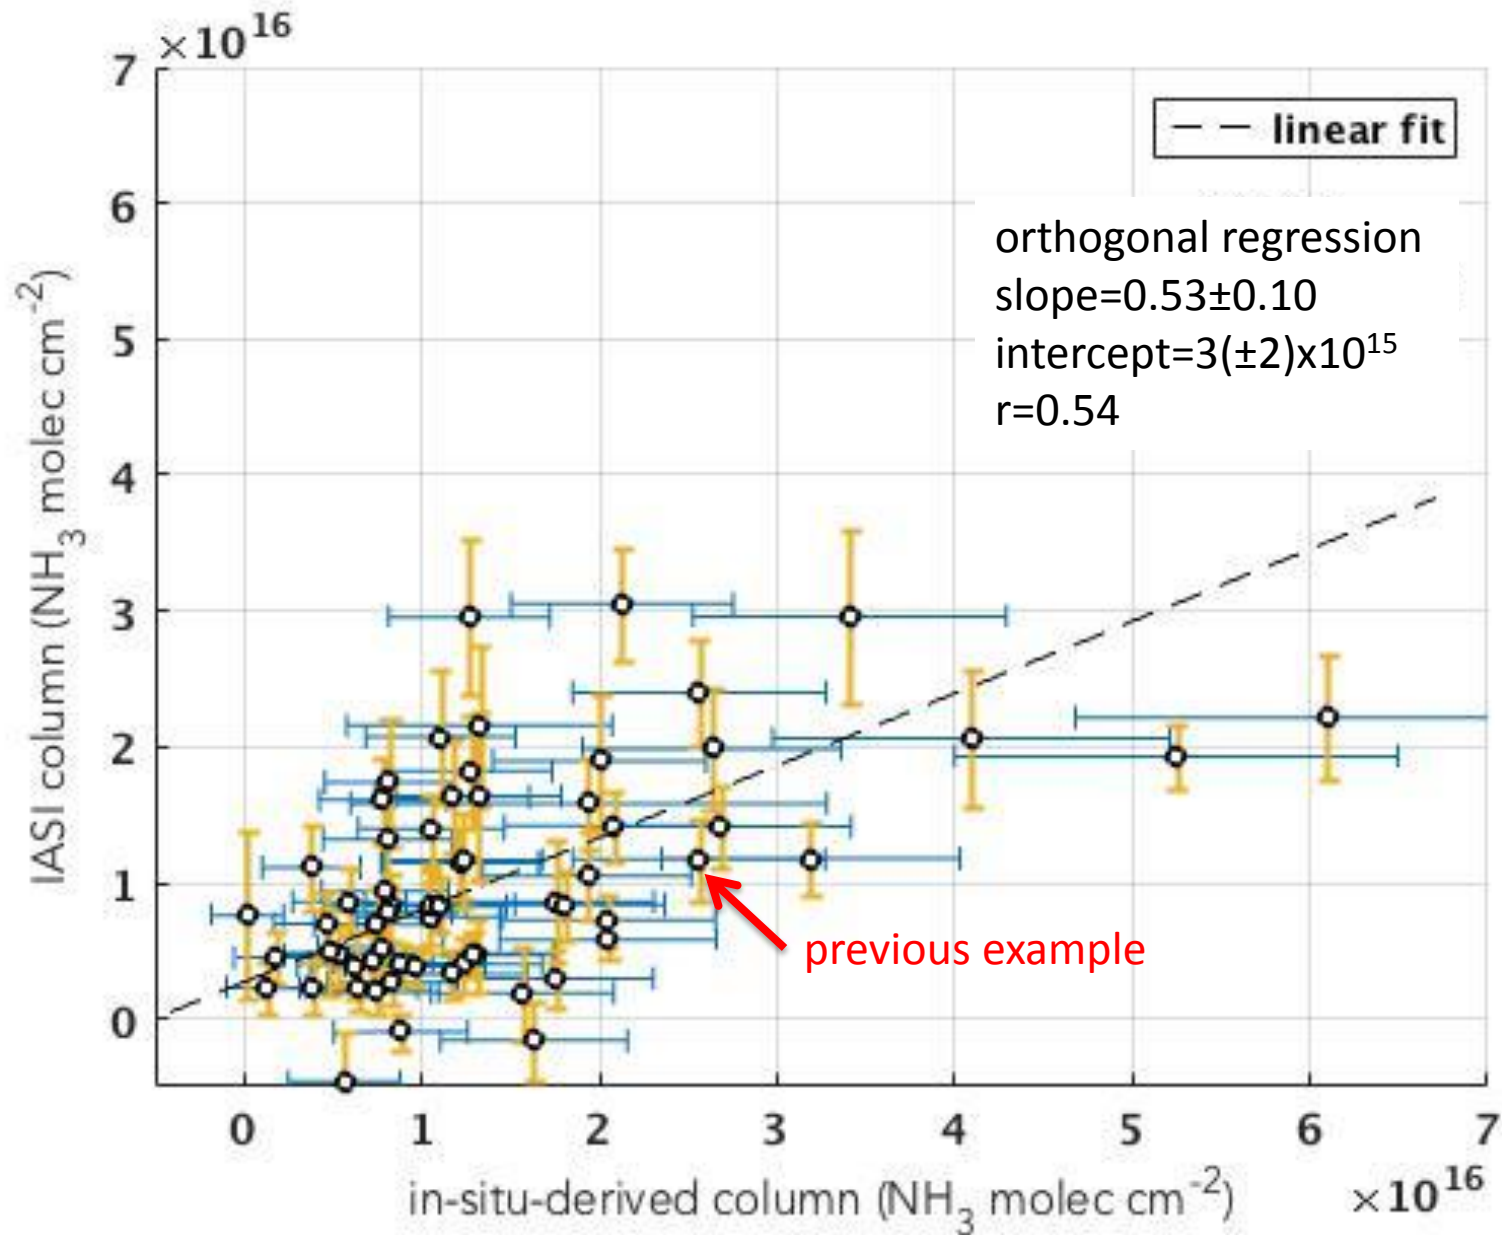

time =  $\pm 60$  min; space =  $\pm 15$  km

Column with no NH<sub>3</sub> above in-situ:  $2.56 \times 10^{16}$   
 Column linearly to 0 at tropopause:  $3.74 \times 10^{16}$

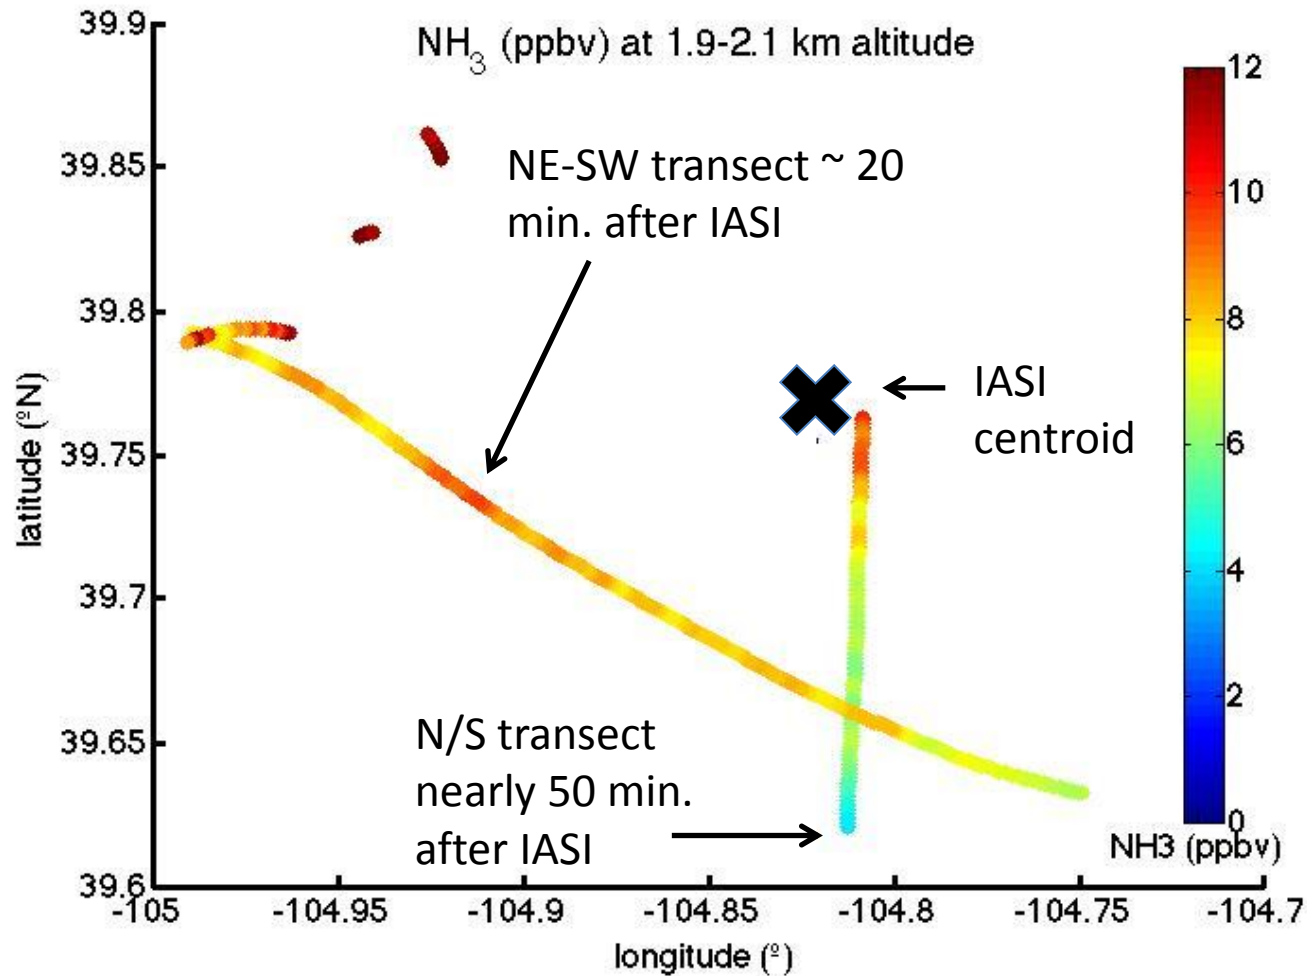

# All DAQ-CO data $\pm 1$ hr, $\pm 15$ km of IASI centroid (N=64)

# Revisit spatial gradient assumption

Restrict to  $2.0 \pm 0.1$  km altitude range where large # data available

NH<sub>3</sub> concentration decreases significantly from NW → SE

Most of the profile is taken much further west and slightly north of IASI centroid

Lower NH<sub>3</sub> air to the E/S may help to explain lower IASI column than aircraft

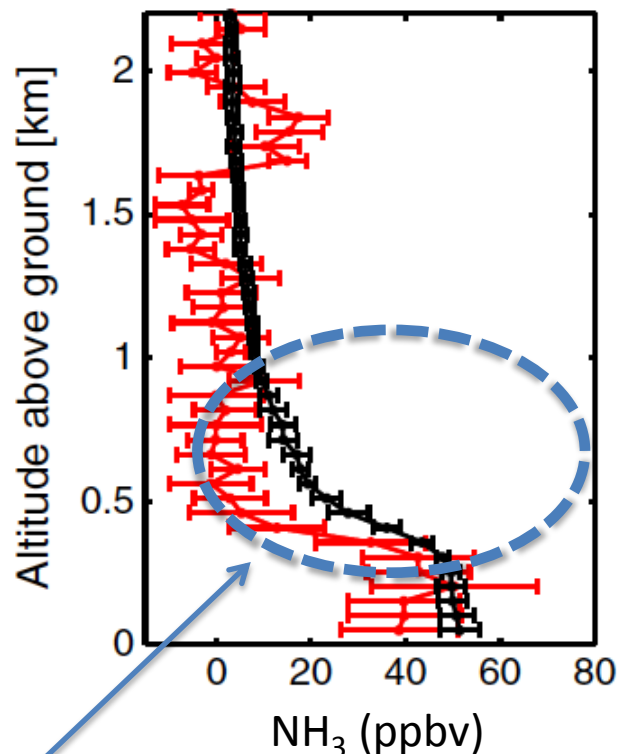

# Revisit $\text{NH}_3$ *in-situ* sampling issues

- $\text{NH}_3$  is very “sticky” to instrument surfaces, degrades accuracy
- inlet problems create poorly-constrained (highly variable) uncertainties

## Aircraft comparison

closed-path PTRMS (Innsbruck)

closed-path (Aerodyne TDL)

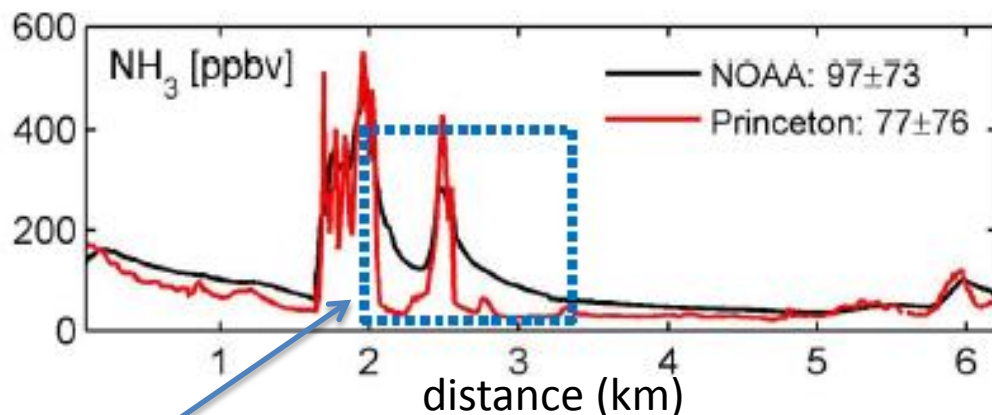

PTRMS responds faster upon spiraling from the polluted boundary layer to the clean, free troposphere but is more imprecise overall than TDL

## Mobile lab intercomparison

open-path (Princeton)

closed-path (Picarro, NOAA CSD)

Open-path shows rapid changes while Picarro lags behind due to outgassing

**In the presence of strong spatiotemporal gradients, need to be careful with the *in-situ* data**

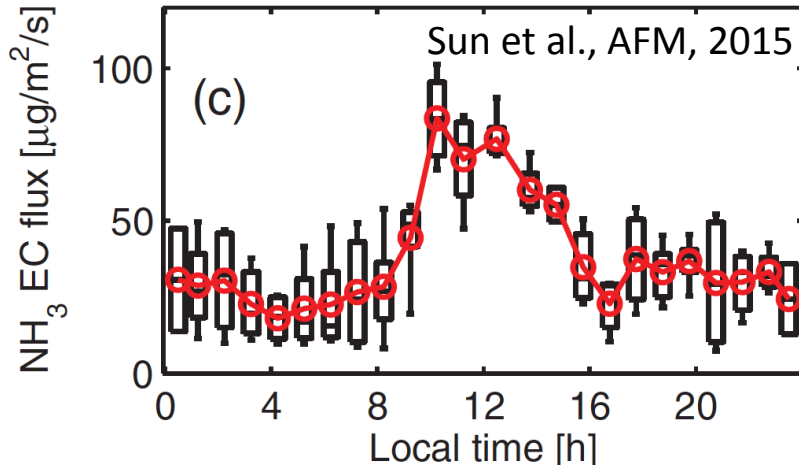

# Sensitivity to space ( $\Delta s$ ) and time ( $\Delta t$ ) windows

correlation (r)			
$\pm \Delta s$ (km)			
	<u>5</u>	<u>15</u>	<u>45</u>
$\pm \Delta t$ (min.)			
20	0.75	0.63	0.19
60	0.59	0.54	0.14
180	0.60	0.53	0.27

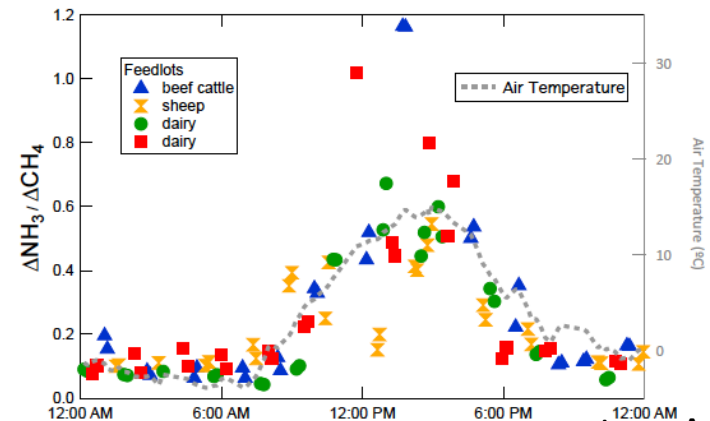

$N$			
$\pm \Delta s$ (km)			
	<u>5</u>	<u>15</u>	<u>45</u>
$\pm \Delta t$ (min.)			
20	8	28	31
60	18	64	101
180	31	229	344

- At 45 km spatial window, correlation degrades significantly at all time windows

Time window is less sensitive but emissions are strongly temp.-dependent:

diurnal  $\text{NH}_3$  fluxes at CO feedlot

courtesy A. Neuman

feedlot  $\Delta\text{NH}_3/\Delta\text{CH}_4$  diurnal cycle

# Summary / implications

- individual IASI  $\text{NH}_3$  columns agree well with in-situ-derived columns ( $m=0.60 \pm 0.10$ ,  $r \sim 0.60$ ,  $b=1 \times 10^{15}$ ), especially given the strong gradients
- first validations at low/moderate  $\text{NH}_3$  abundances ( $10^{15} - 10^{16}$  molec  $\text{cm}^{-2}$ ) (one order of magnitude lower than previously shown)
- IASI  $\text{NH}_3$  can be used with confidence to capture spatial gradients on daily timescales and at moderate column abundances for DAQ-CO

## Future validation needs

- uncertainties of free tropospheric  $\text{NH}_3$  are significant at low column abundances
- in-situ measurement hystereses and biases problematic for columns
- sensitivity to variations in thermal contrast (ocean, night)

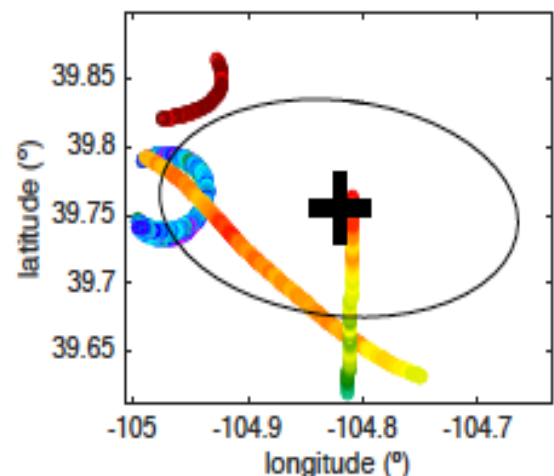

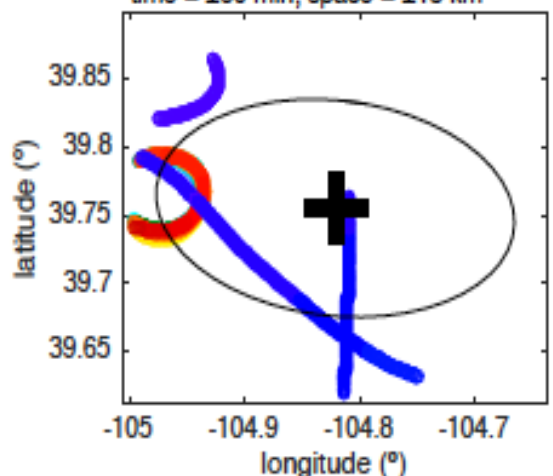

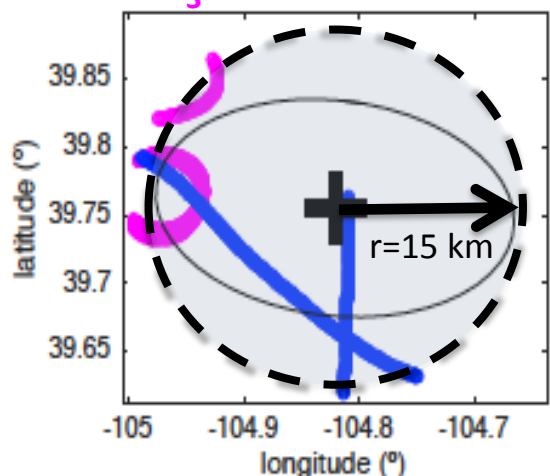

C-130 NH<sub>3</sub>

P-3B NH<sub>3</sub>

NH<sub>3</sub> col:  $1.17 \times 10^{16}$  molec cm<sup>-2</sup>  $\pm 25.6\%$  i=213 fov=110°

time =  $\pm 60$  min; space =  $\pm 15$  km

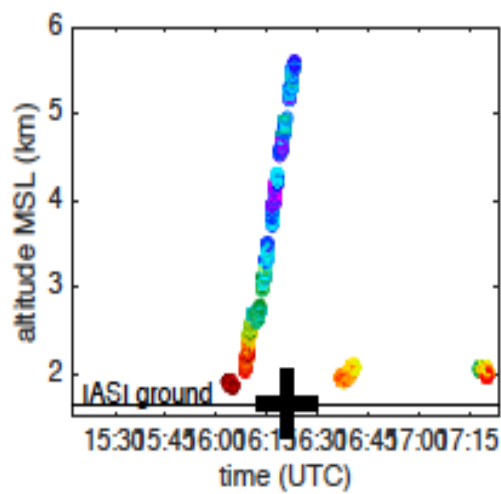

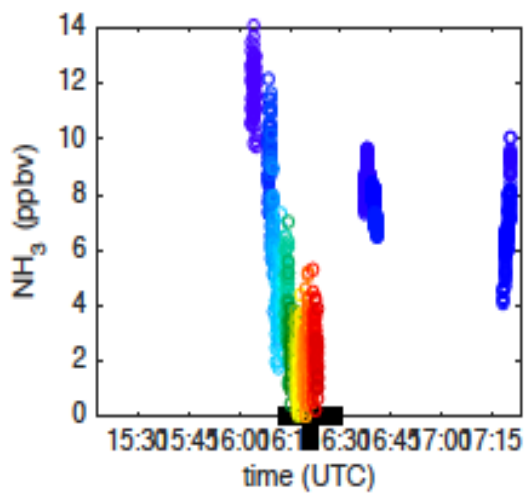

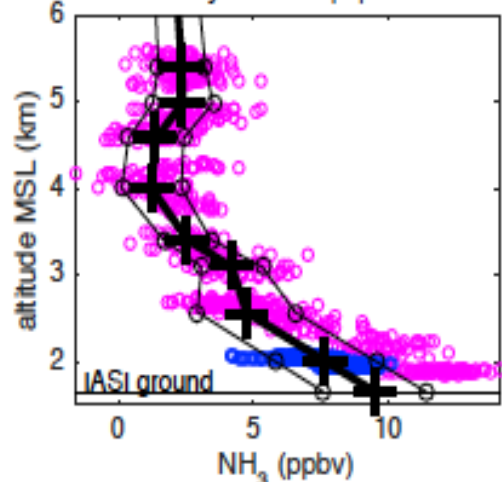

type of data

altitude MSL (km)

NH<sub>3</sub> (ppbv) (max=2X median if > 5 ppbv)

Column with no NH<sub>3</sub> above in-situ:  $2.56 \times 10^{16}$

Column linearly to 0 at tropopause:  $3.74 \times 10^{16}$

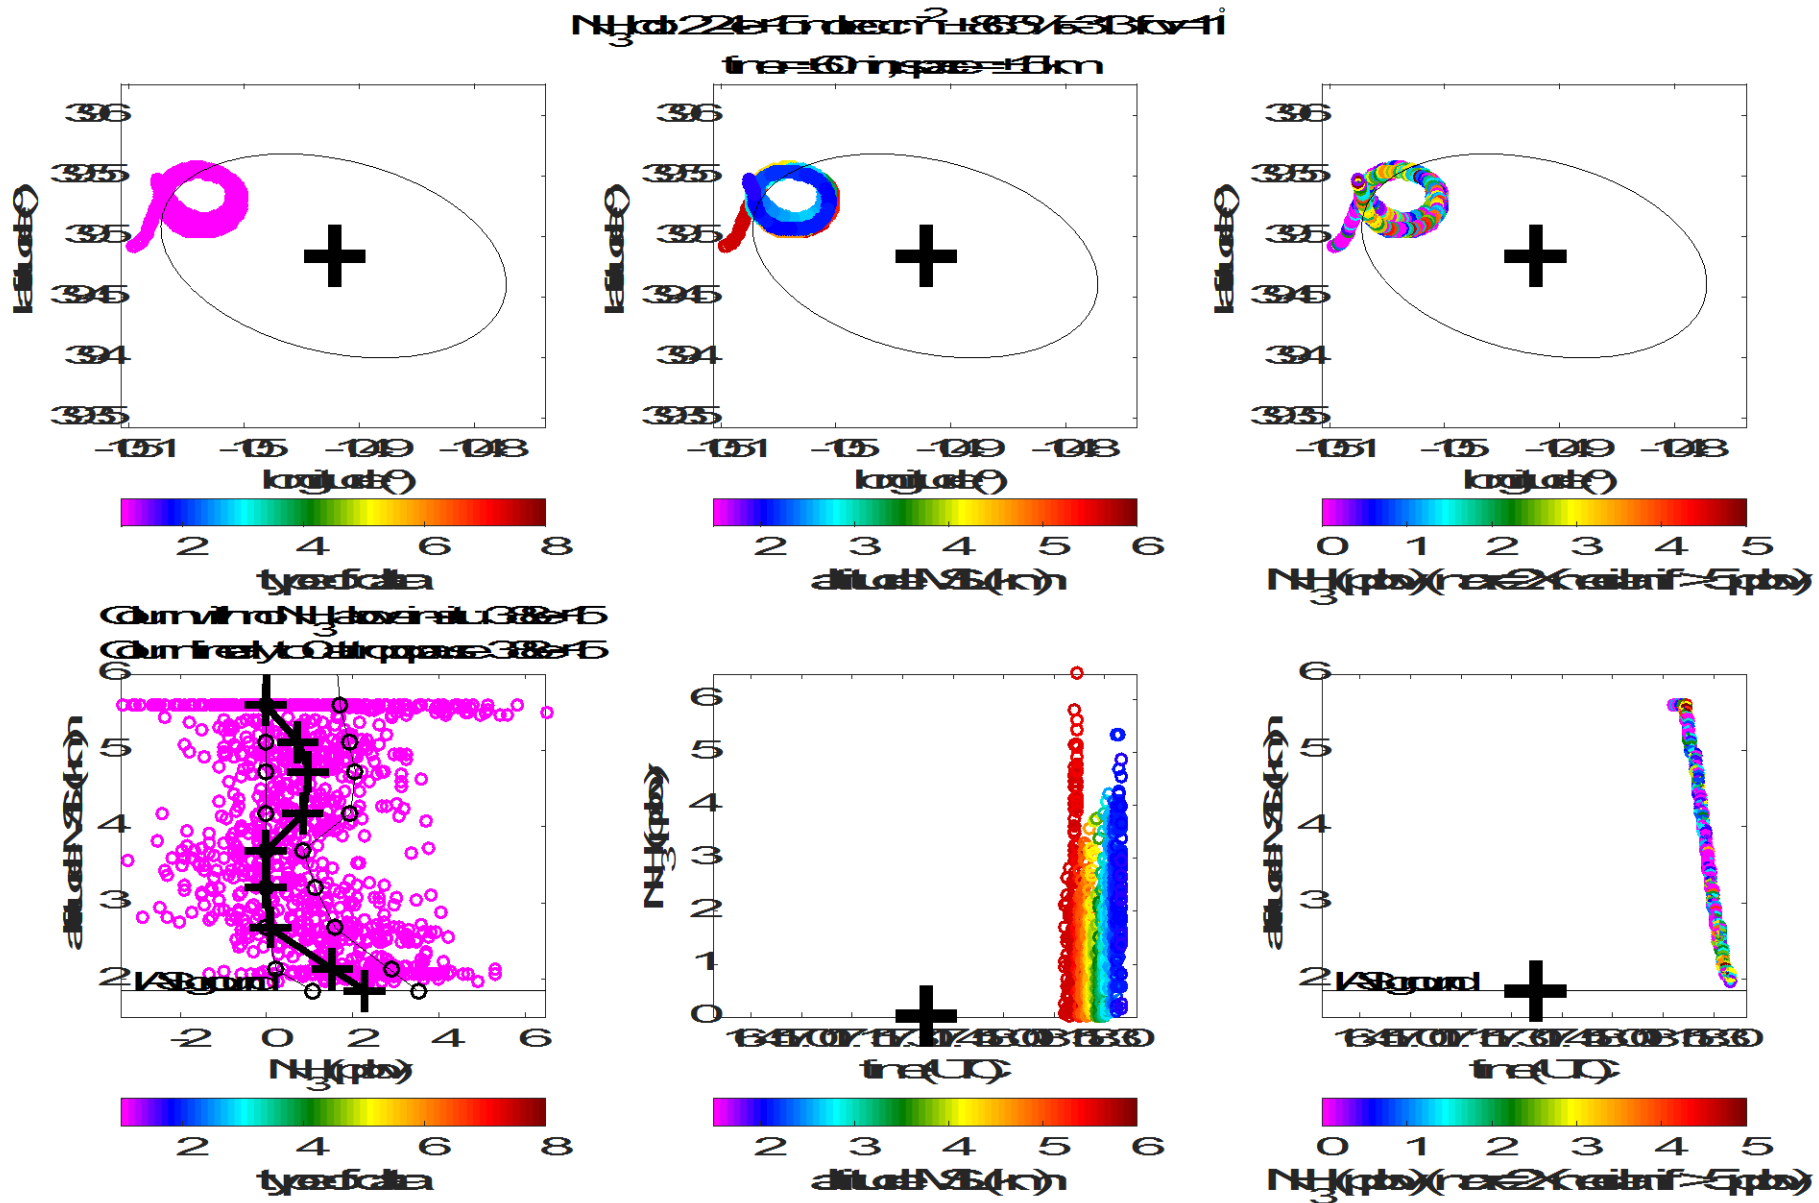

type of data

altitude MSL (km)

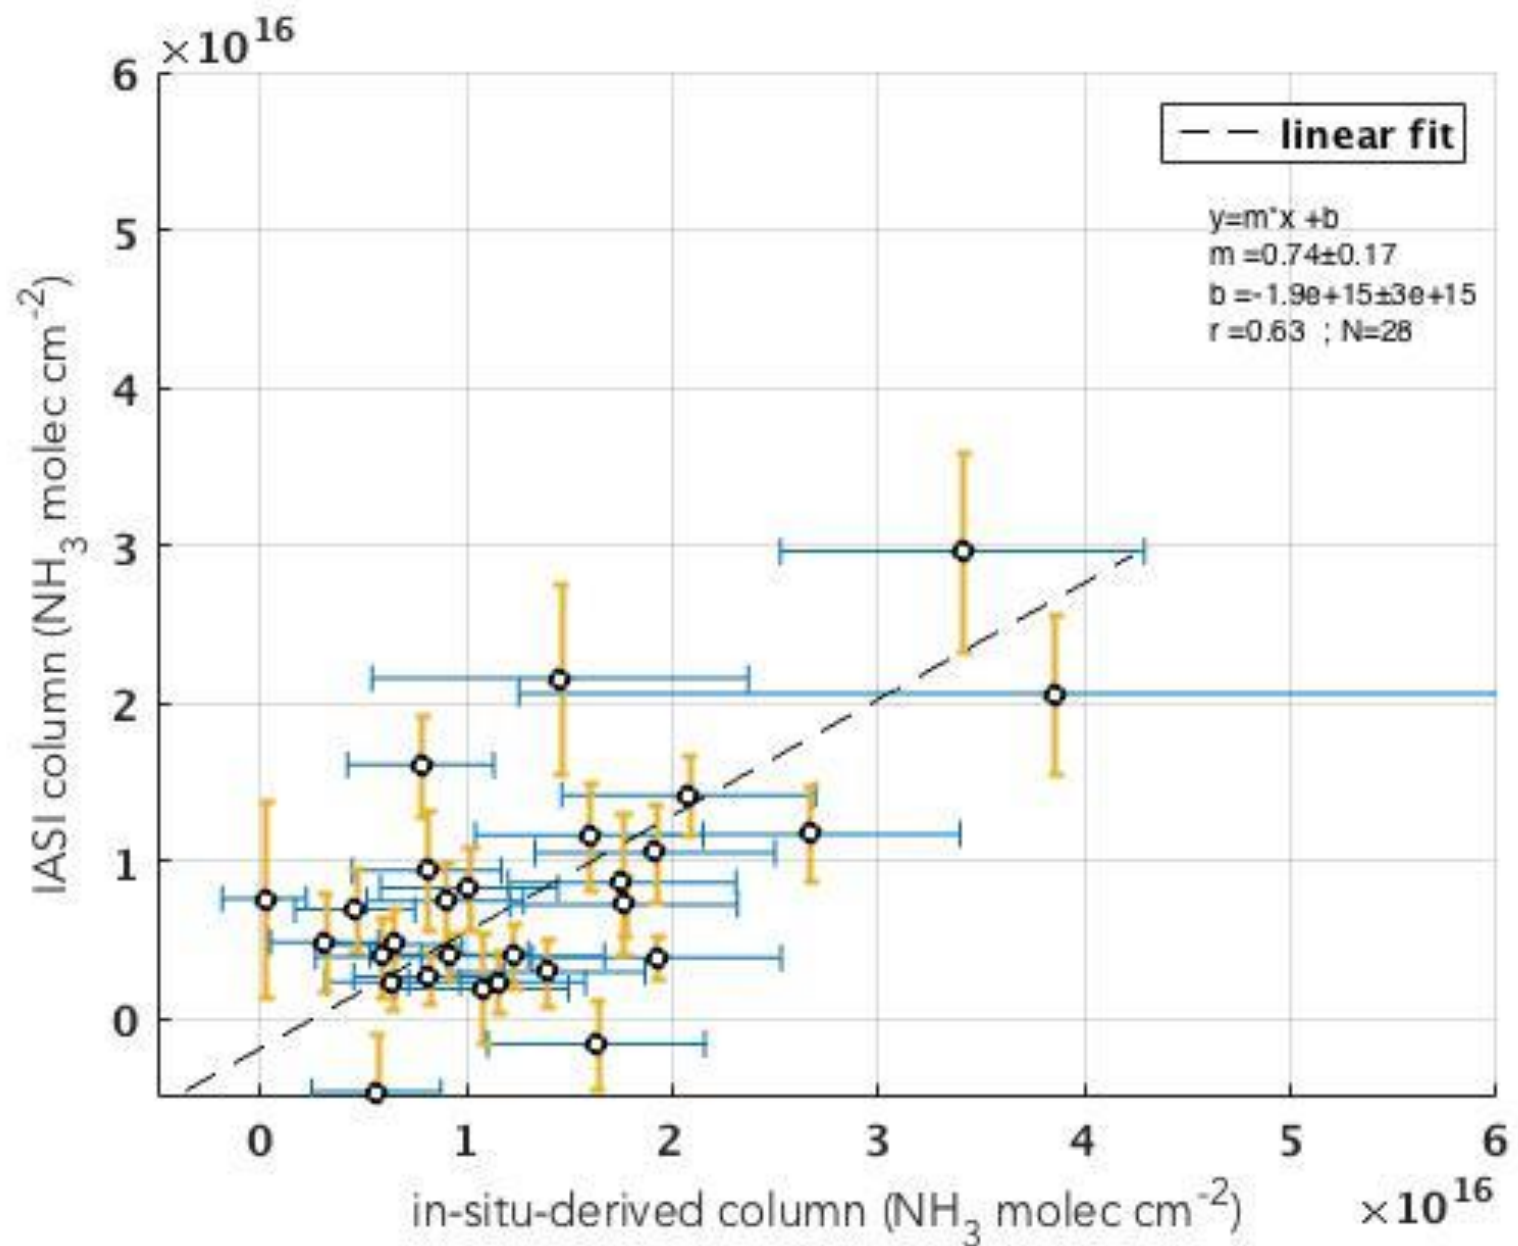

NH<sub>3</sub> (ppbv) (max=2X median if > 5 ppbv)

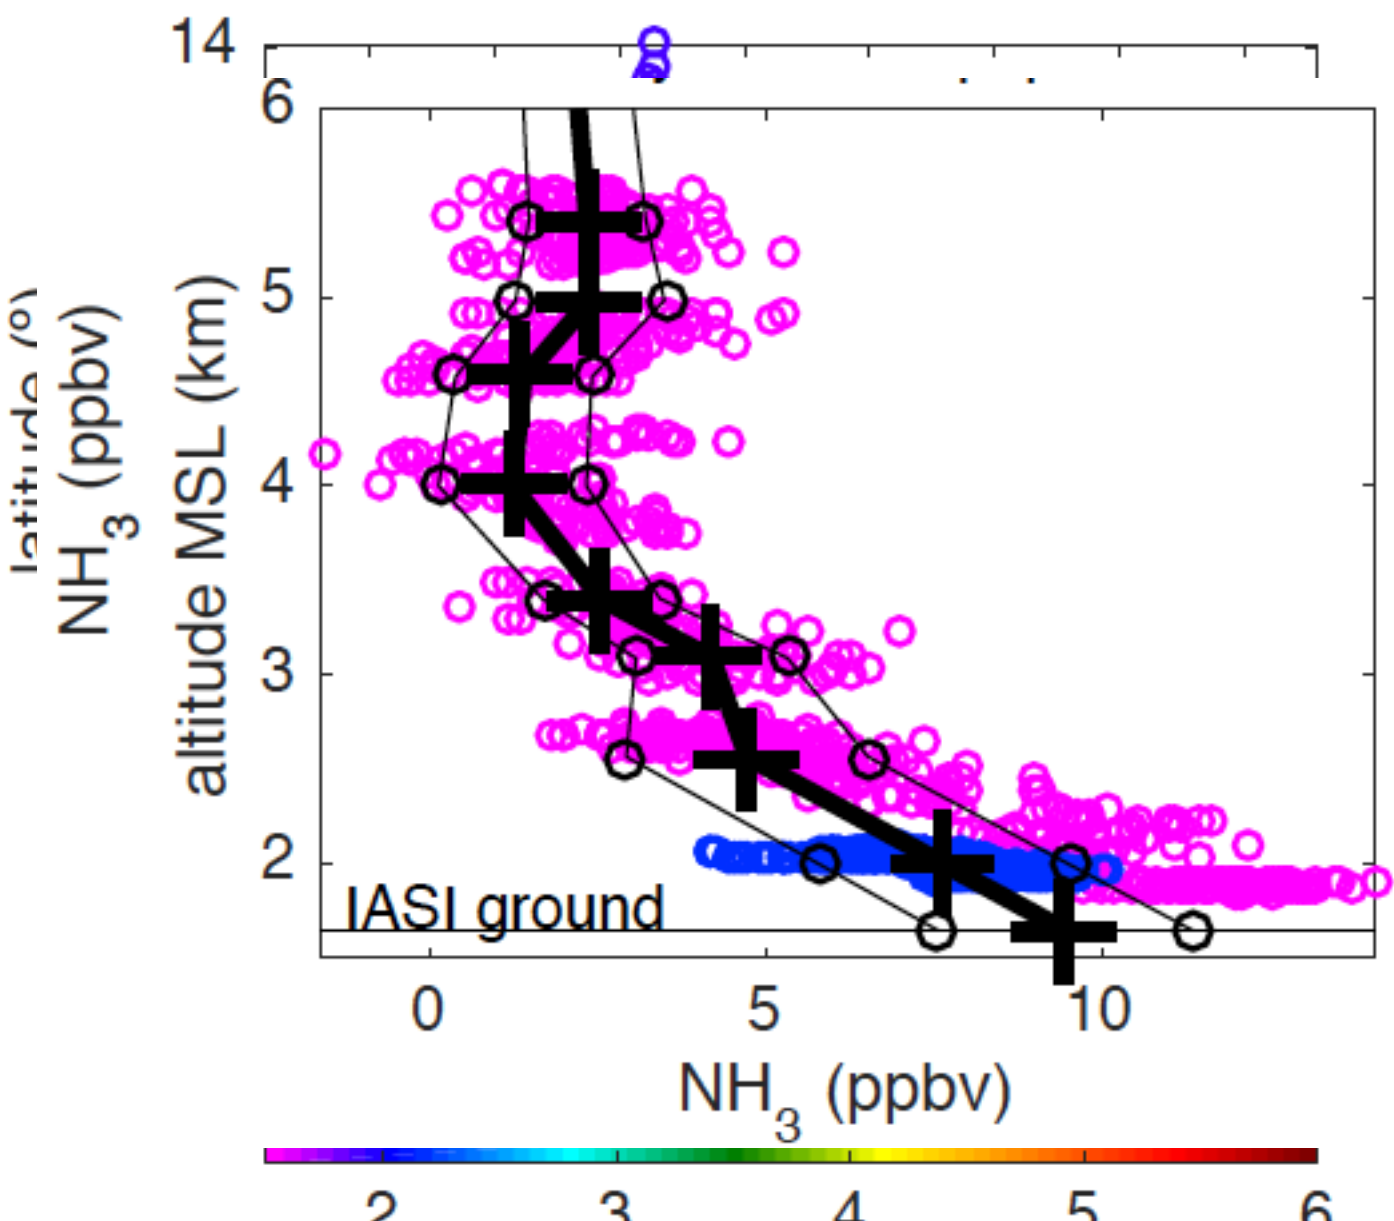

# Low column (low $10^{15}$ ) example

Validation at low columns; in-situ likely suffering from sampling biases

$\pm 15\text{km}$ ,  $\pm 20\text{ min}$

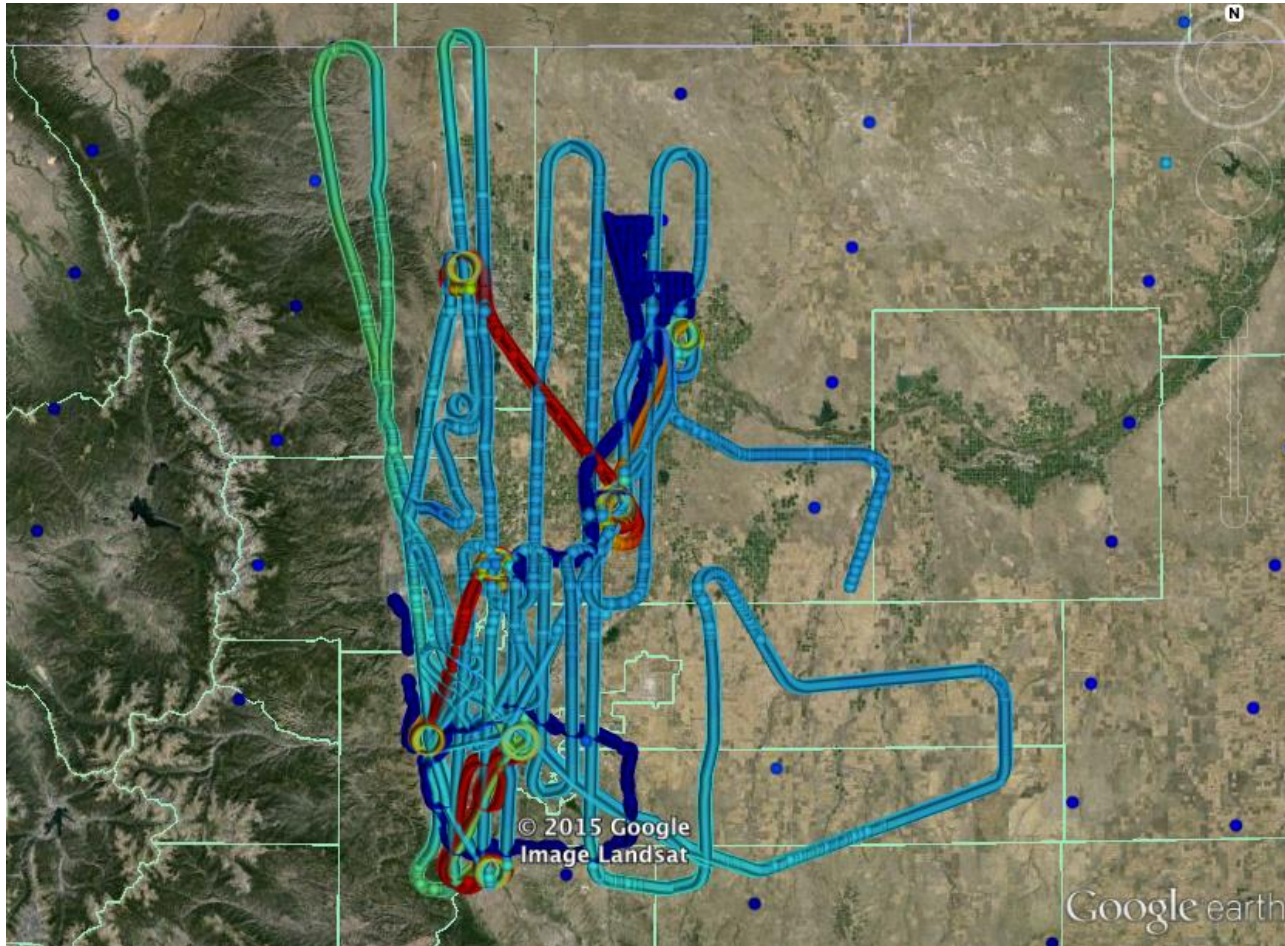

# Case study of July 28, 2014

Extensive set of aircraft/ground measurements:

N=261 IASI; N=149 (filtered); N=8 for  $\pm 1$  hour,  $\pm 15$  km of aircraft data

(comparable scales of  $\Delta s$ ,  $\Delta t$  with wind of  $4 \text{ m s}^{-1}$ )

(colors here represent  $\sim$  altitude (dk. blue = ground; red=5 km)

## Intrapixel variability:

# Field experiments

**NASA DISCOVER-AQ (Colorado):** Deriving Information on Surface Conditions from Column and Vertically Resolved Observations Relevant to Air Quality

- focus on vertical profiles, satellite validation, air quality modeling
- July 17 - Aug. 12, 2014
  - P3-B and B200 aircraft, mobile labs, tower, ground sites, soundings (16 P3-B flight days)

**NSF FRAPPE:** Front Range Air Pollution and Photochemistry Experiment

- focus on photochemistry, spatiotemporal gradients
- July 26 – Aug. 18, 2014
- separate but coordinated study on NSF C-130, mobile labs, tower (15 C-130 flight days)

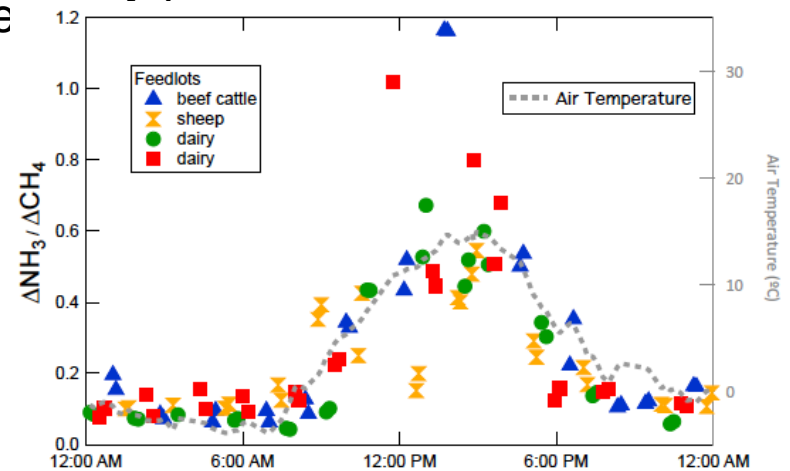

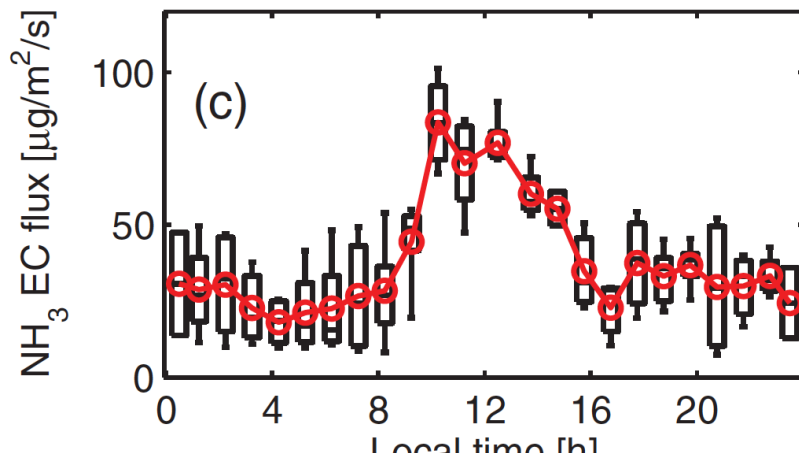

# Sensitivity to space ( $\Delta s$ ) and time ( $\Delta t$ ) windows

	slope (m) $\pm \Delta s$ (km)		
	5	15	45
$\pm \Delta t$ (min.)			
20	0.62	0.74	0.04
60	0.16	0.53	0.14
180	0.66	0.99	0.14

	correlation (r) $\pm \Delta s$ (km)		
	5	15	45
$\pm \Delta t$ (min.)			
20	0.75	0.63	0.19
60	0.59	0.54	0.14
180	0.60	0.53	0.27

- At 45 km spatial window, correlation degrades significantly at all time windows

Time window is less sensitive but one must be

N=8 cases with in-situ data  $\pm 1$  hr,  $\pm 15$  km of an IASI centroid for July 28  
(respective IASI labeled 'Point 1' in each graph below)

072814:  $\Delta s = \pm 15$  km,  $\Delta t = \pm 1$  hr (mean wind  $4 \text{ m s}^{-1}$  @ one hour = 14.4 km)  
(autoscaled color here, so disregard)

# **Sensitivity spatiotemporal window**
