### Introduction

With the launch of AIRS in 2002, the operational assimilation of hyperspectral IR radiances allowed a considerable advance in Numerical Weather Prediction (NWP) models. For example at Météo-France, the three operational hyperspectral IR sounders (AIRS, IASI and CrIS) provide more than 68% of the total number of observations into the French global NWP ARPEGE model and contribute to more than 25% in modifying the assimilation system. The high spectral resolution of these instruments have greatly contributed to improve temperature and humidity profiles sensitivity. To reach operational requirements, the fast RTTOV model was constantly improved through the NWP SAF project. Furthermore, RTTOV makes an effort for being ahead in research developments to support NWP such as surface, clouds and aerosols IR modeling or coefficients generation for past instruments or for future instruments.

### Status

The current version of RTTOV (11.3) allows the simulation of TOA radiances or Brightness Temperatures for hyperspectral IR sounders listed in Table 1. The fast simulations are based on calculations of atmospheric transmittances using instrument-dependent coefficients. These coefficients are generated from:

- A training dataset of 83 diverse profiles of H2O, O3, CO2, N2O, CO, CH4, O2, NO, SO2, NO2, HNO3, OCS, N2O, COINO3, CFC-11, CFC-12 et CFC-14
-LBLRTM version 12.2 (AER 3.2 spectroscopic database and MTCKD 2.5.2 for continuum).

3 versions of coefficients are provided on 54 or 101 layers:
- Old: H and O3 are variable gas, other are fixed gas
- Old: V8: H2O, O3 and CO2 are variable gas, other are fixed gas
- V9: H2O, O3, CO2, N2O, CO, CH4 are variable gas, other are fixed gas

Surface, clouds and aerosols modeling

Surface, cloud and aerosol models provided in RTTOV are given in Table 2. Aerosol and cloud scattering are based on the Chou-scaling approximation. The Figure 2 shows IASI-like typical spectra difference between reference spectra (clear-sky and fixed surface emissivity of 0.98) and UWIREMIS atlas (blue), ice cloud (red), liquid cumulus cloud (green) and desert dust (purple).

Other capabilities

RTTOV simulations also include the following capabilities:
- Non Local Thermodynamic Equilibrium (NLTE) effect based on CRTM model.
- Solar scattering based on single scattering approximation.
- Principal Component-based simulations (PC-RTTOV).

Examples on IASI-like spectra are shown on Poster S8-B8 “Learning from IASI with RTTOV-GUI”

### Developments for RTTOV 12

The version 12 of RTTOV is planned to be released in December 2016. The new developments for hyperspectral IR sounders will include:
- Adding SO2 as a variable gas: involve predictor definition and create training profiles.
- Adding an option to choose clouds (LWC/IWC or mixing ratio) and aerosols (number density or mixing ratio) unit to be in-line with NWP and MACC products.
- Removing old ice cloud parameterisations, only the parameterisation based on the Baran database will remain.
- Updating IR sea surface emissivity model.
- Updating IR land surface emissivity atlas (UWIREMIS).
- Interfacing with the radiative transfer model HT-FRTC that includes full scattering model.
- Addressing the variations in CO2, CO2, N2O and CH4 concentration for whole satellite era.
- Adding new PC-RTTOV coefficients (incl. NLTE, all trace gases and aerosols).
- Calculating coefficients for new instruments (i.e., SI-1, CLARREO).
